The pharmacokinetics of diflunisal, a new salicylic acid derivative with analgesic and anti-inflammatory properties, was investigated in Sprague-Dawley rats. The oral absorption of the drug was characterized by a relatively rapid absorption ($t1/2 = 0.9 +/- 0.1$ h) and a short Tmax ($1.7 +/- 0.3$ h). The volume of distribution at steady state was $0.67 +/- 0.18$ l/kg, and the total clearance was $13.3 +/- 1.5$ ml/min/kg. Diflunisal exhibited only a low level of protein binding (less than 10%). Following administration of the drug, the rat liver metabolized diflunisal to the 2-hydroxy derivative of salicylic acid. The unmetabolized drug was undetectable in urine or feces, thus representing a minor pathway for elimination of diflunisal. The systemic clearance (CLsys) of the 2-hydroxy derivative ($71.7 +/- 8.6$ ml/min/kg) was significantly lower than that of diflunisal (CLsys = $13.3 +/- 1.5$ ml/min/kg, P less than.001). The half-life of the metabolite was longer than that of the parent drug ($t1/2 = 4.9 +/- 0.8$ h vs. $t1/2 = 0.9 +/- 0.1$ h, P less than.05). The 2-hydroxy derivative exhibited much higher binding to rat liver microsomes (Bmax = $87 +/- 7$ pmol/mg of protein, Km =
