People who have used Windows for decades might find it hard to understand Microsoft's reasons for moving away from the Windows legacy code base. The software industry has spent the last few decades demanding constant improvement. For a long time, Microsoft's legacy code base was simply not good enough to meet the needs of many apps that have been created over a prolonged period of time. Microsoft has long been in the habit of saying that it does not want to spend huge amounts of money on fixing problems in a code base that is many years old. But with the release of Windows 10 due out later this year, the situation has reached the point where the massive task of digging out the legacy code will be much harder. Microsoft will have to recompile entire chunks of the Windows code base, so changes will be required to everything from the UI to the underlying code. The company will not just want to replace old code; it will want to keep what works. It seems a tremendous task, but other operating system makers have similar problems. Apple has had to completely rebuild the operating system for iOS in recent years, and Google, with its Android operating system, has made similar updates, so Microsoft will not be alone. The situation will get worse as Microsoft wants to introduce new features that it has neglected while working on the new code base. The company has just published a list of features that will not be present in Windows 10, including Cortana, the new operating system's voice search. Microsoft has always talked about Windows as a collection of apps, not a single platform. An operating system is not about a rigid set of APIs, as Linux is, but a way of providing an interface to apps. To build Windows 10 will therefore require the company to change the code base to support the new way apps will work. For the first time, Windows will have a new UI framework in the form of its Windows Runtime (WinRT), as Windows now has a completely different way of presenting an c6a93da74d
